

The scenario

1. Company Background

WheelsBazaar is an online used-car marketplace operating across India (similar to Cars24, CarDekho, or Spinny). Sellers list their vehicles on our platform, and buyers browse, compare, and purchase. We currently handle roughly 5,000 listings per month across metros and tier-2 cities.

2. Business Problem

Today, sellers set their own asking price, and our operations team manually reviews listings that "look off." This causes three measurable problems:

1. **Overpriced listings sit unsold.** Cars priced more than ~15% above market value take 3x longer to sell, clogging inventory and hurting buyer trust in the platform.
2. **Underpriced listings cost sellers money** — and generate complaints when sellers later discover they sold below market. This damages retention.
3. **Manual review doesn't scale.** Our pricing analysts can review ~40 listings a day. At 5,000 listings/month we review less than 25% of inventory.

We also plan to launch an **instant-buy program** (WheelsBazaar Direct) where the company purchases cars directly from sellers. For this, we need an automated, trustworthy price estimate a wrong estimate here loses the company real money on every transaction.

Requirements

Build a machine learning model that predicts the **fair market price** of a used car from its attributes (make, model, year, kilometers driven, fuel type, transmission, ownership history, engine specs, location, etc.).
